Amaura Labs — Partial Business Opportunity Research Report

Status: Partial report only
Research date: October 4, 2026
Coverage: The workflow spawned 50 research subtasks. It completed 40 agent tasks, but 10 failed before completion and the lead synthesis task did not run. Of the completed work, 16 detailed evidence files were preserved and are used here. This report therefore does **not** claim complete coverage of the original 20–40 Amaura opportunities and 30–50 cash-cow opportunities.

Executive Summary — Interim Findings

1. Is there a commercially promising business around the Amaura thesis?

Yes, but not as a generic "AI discovers algorithms" company. The evidence points toward a narrower thesis:

> **Amaura can create commercial value where a customer has an expensive, measurable optimization or verification problem, a repeatable execution environment, and a reliable evaluator.**

The most promising early categories are:

1. **AI-agent evaluation and optimization infrastructure**
2. **Coding-agent and AI-generated-code verification**
3. **Inference and cloud-cost optimization for customers with meaningful compute spend**
4. **CI/CD and test-suite optimization**
5. **Narrow operational optimization services that create data and evaluators**

The common economic requirement is not merely that an AI system can generate candidates. It is that the customer can trust the evaluator enough to deploy or pay for the selected result.

2. Three strongest possibilities identified so far

1. **Production agent-evaluation and workflow optimization:** Strong evaluator fit, recurring need, and visible customer spending. Competition is intense, but the market is still developing and current evaluations remain incomplete.

2. **AI-generated-code verification and approval infrastructure:** Strong pain and high trust value. A product that produces auditable evidence rather than another code-review opinion could be differentiated, although GitHub, Sonar, Qodo, CodeRabbit, and frontier-model vendors are powerful competitors.
3. **Inference/cloud optimization for AI-heavy companies:** Direct economic value and measurable benchmarks. The problem is real, but cloud vendors, NVIDIA, open-source stacks, and established FinOps vendors are aggressively expanding into it.

3. Is Amaura itself worth pursuing commercially?

Worth pursuing as a focused product experiment, not yet justified as a broad platform company. Amaura's experiments provide credible evidence that generate → execute → evaluate → select → verify can discover useful policies across graph coloring, scheduling, and production-like traces. They do not yet establish a moat, universal superiority, or willingness to pay.

The commercial test should be narrow: choose one evaluator-rich workflow, obtain real customer data, and prove an economically meaningful improvement under unseen or production-like conditions.

4. Strongest cash-cow opportunity identified so far

A narrow productized operations service, especially vendor onboarding/procurement operations or specialized lead research, is more likely to produce early cash than a new SaaS product.

Among the preserved evidence, vendor onboarding is especially attractive because it has recurring workflow volume, explicit documents and approval states, measurable cycle-time/completeness metrics, and a plausible India-to-global delivery model. It is not highly defensible as generic software or BPO. It should begin as a tightly scoped service with automation behind the scenes.

5. Recommended path

Pursue an adjacent cash cow while running a narrowly scoped Amaura validation project. Do not build a general optimization platform first. Use the service to acquire customers, workflow data, evaluators, and operating cash. Build only the internal automation that improves margins or produces a measurable optimization capability customers may later buy.

6. What I would do in the founder's position

I would sell a fixed-scope, human-in-the-loop operational service to a narrow B2B niche within 30 days, while separately interviewing AI infrastructure and agent-platform teams

about an evaluation/optimization pilot. The service provides cash and distribution; the Amaura pilot tests whether the core technology can produce a result customers will pay for.

Part I — Amaura Business Opportunities

1. Amaura thesis assessment

Amaura’s strongest commercial abstraction is:

```
Define objective + constraints + evaluator
→ generate candidates
→ execute candidates safely
→ measure outcomes
→ reject invalid candidates
→ select and verify improvements
```

This fits best when:

- the objective is measurable;
- candidate execution is sandboxed or reversible;
- the evaluation set can be held out from search;
- improvement has a clear economic value;
- the workflow repeats as workloads, models, code, or constraints change.

It fits poorly when quality is mainly subjective, feedback is slow, deployment is dangerous, or the evaluator can be gamed.

Amaura’s own evidence makes evaluator design a first-order product issue. The production-like cloud-trace work transferred successfully on static workloads but degraded under churn and node draining. The commercial implication is direct: a product must optimize the real operating environment, not a convenient synthetic proxy.

2. Market map

A. AI evaluation and agent infrastructure

This is already an active market. LangSmith, Braintrust, Langfuse, Maxim, Galileo, Arize, and cloud-provider platforms offer tracing, datasets, evaluators, trajectory analysis, and

production monitoring. Current pricing ranges from free tiers and low monthly plans to enterprise contracts. LangSmith lists a free Developer tier and a Plus tier at $39 per seat per month; Braintrust lists Pro at $249 per month; Langfuse lists Core at $29, Pro at $199, and Enterprise at $2,499 per month. Sources: [1] [2] [3]

The opening is not "add evaluations." It is potentially **automatic search over agent configurations, tools, prompts, routing policies, and workflows using customer-specific evaluators**, with reproducible evidence of improvement.

B. Coding-agent verification

AI-generated code is increasing the value of testing, security review, regression detection, and human oversight. GitHub's own documentation warns that Copilot-generated output can contain quality and security problems and requires review and testing. A 2025 Veracode study reported that only 55% of tested AI-generated code was secure across its test design. Sources: [4] [5]

The category is crowded. GitHub Advanced Security, CodeRabbit, Qodo, Greptile, Sonar/Gitar, Aviator Verify, and testing platforms already sell adjacent products. A defensible Amaura wedge would need to produce **execution-backed verification evidence** rather than another probabilistic review score.

C. Inference and cloud optimization

AI inference costs vary by provider, hardware, model, batching, routing, caching, and utilization. Public infrastructure pricing makes the economic value visible: Modal lists H100 compute at approximately $3.95 per hour, while Replicate lists H100 at $5.49 per hour and A100 at $5.04 per hour. Sources: [6] [7]

However, the technical surface is rapidly commoditizing. vLLM, NVIDIA Dynamo, TensorRT-LLM, AIBrix, llm-d, AWS SageMaker, and Google Cloud guidance already cover routing, batching, caching, quantization, autoscaling, and serving optimization. Sources: [8] [9] [10] [11]

FinOps also has strong native competition. AWS Cost Optimization Hub, Google Active Assist, Vantage, Kubecost/OpenCost, CloudZero, CAST AI, nOps, and ProsperOps are established alternatives. Sources: [12] [13] [14] [15]

D. Application and CI/CD performance

Application-performance optimization has proven recurring spend. Datadog, New Relic, Dynatrace, Grafana, Sentry, Blackfire, and Polar Signals sell profiling, tracing, performance monitoring, and related tooling. Public plans range from free tiers to enterprise contracts;

Datadog lists APM at roughly $31–$36 per host per month and Continuous Profiler at roughly $19 per profiled host per month on annual plans. Source: 16

CI/CD optimization has a concrete evaluator: build time, test time, failure rate, compute cost, and time to feedback. CircleCI reports that its 2026 Q2 analysis of 20 million workflows found elite organizations increasing main-branch throughput while reducing cost per shipped change, although the company' s specific savings claims are vendor evidence. CloudBees Smart Tests, Harness, Trunk, Develocity, and GitHub Actions already compete in test selection, flaky-test handling, caching, and workflow optimization. Sources: 17 18

E. Physical operations optimization

Logistics, warehouse, inventory, energy, and scheduling have strong objective functions, but integration and sales cycles are harder. Routific lists prices from free for low volume to $150 per month and per-order tiers; Onfleet lists plans from $619 to $3,099 per month; Google Route Optimization API offers a paid API, while OR-Tools is free and open source. Sources: 19 20 21

Warehouse systems are more enterprise-heavy. Indicative vendor research places cloud WMS costs from roughly $2,000 per month for small deployments to $10,000 per month for enterprise, plus implementation. Source: 22

Energy has measurable value, but control-system integration and trust are significant barriers. NIST describes US commercial buildings as consuming roughly $190 billion in annual energy and notes that HVAC accounts for approximately 35–40% of building energy use. Source: 23

3. Preserved Amaura opportunity findings

The table below is **provisional** and limited to the categories for which detailed evidence was preserved.

Opportunity	Specific buyer	Evidence of pain/value	Existing competition	Evaluator quality	Amaur
Agent trajectory/workflow optimization	VP AI/Product or Head of Applied AI at an AI product company	Tool calls, task completion, latency, cost, reliability, and trajectory quality can be measured; current evaluation	LangSmith, Braintrust, Langfuse, Maxim, Galileo, Arize, cloud platforms	8/10	9/10

		remains incomplete			
Coding-agent benchmark and regression evaluation	VP Engineering or developer-platform lead	Benchmarks are becoming stale or contaminated; fresh tasks and production regression are needed	SWE-bench ecosystem, Braintrust, LangSmith, OpenAI Evals, Qodo	8/10	9/10
AI-generated-code verification gate	CTO, VP Engineering, security/compliance owner	AI code needs tests, security checks, approval evidence, and human oversight	GitHub, CodeRabbit, Qodo, Greptile, Sonar/Gitar, Aviator Verify	8/10	8/10
Inference serving optimization	VP Infrastructure at an AI company spending materially on GPUs	Batching, routing, caching, quantization, and hardware choices directly affect cost and latency	vLLM, NVIDIA, AWS, Google, Baseten, Modal, Fireworks, Together, CAST AI	9/10	9/10
Cloud-cost/performance optimization	FinOps leader, CTO, or VP Infrastructure	AI spend and cloud waste are major priorities; optimization recommendations and automation are expanding	AWS, Google, Vantage, Kubecost, CloudZero, CAST AI, nOps, ProsperOps	9/10	8/10
Continuous backend performance optimization	VP Engineering or SRE leader	Profiling and production bottlenecks recur continuously; improvements affect infrastructure and user experience	Datadog, New Relic, Dynatrace, Grafana, Sentry, Blackfire, Polar Signals	8/10	8/10

CI/CD and test-suite optimization	Engineering productivity or platform lead	Build/test delay, flaky tests, and compute cost are measurable and recurring	Harness, CloudBees, Trunk, Develocity, CircleCI, GitHub Actions	9/10	8/10
Logistics routing optimization	COO/operations leader at delivery-heavy firms	Mileage, routes, time windows, fleet use, and SLA can be evaluated	Routific, OptimoRoute, Onfleet, Google, Samsara, Locus, FarEye	9/10	7/10
Warehouse labor/inventory optimization	COO, warehouse director, supply-chain VP	Labor shortage, slotting, replenishment, and dead stock have clear costs	Blue Yonder, Manhattan, Infios, Netstock, Inventory Planner	8/10	7/10
HVAC/building energy optimization	Building owner/operator or energy manager	Energy savings are measurable; smaller buildings lack controls and expertise	C3 AI, BrainBox, BEMCS vendors, controls integrators	7/10	6/10

Provisional Amaura ranking

Scores below use the requested dimensions but are **interim judgment scores**, not the final 20–40-opportunity ranking.

Rank	Business	Provisional score / 10	Why it ranks here
1	Agent evaluation and workflow optimization	8.3	Strong technical fit, recurring demand, measurable but imperfect evaluators
2	Coding-agent benchmark and regression infrastructure	8.1	Fresh-benchmark need and high strategic relevance

3	AI-generated-code verification with execution evidence	7.9	High pain and trust value; strong incumbents
4	Inference serving optimization	7.8	Direct economics and excellent evaluator; cloud/open-source threat is severe
5	CI/CD and test-suite optimization	7.7	Excellent evaluator and recurrence; incumbent density is high
6	Cloud cost/performance optimization	7.6	Strong pain and willingness to pay; native cloud competition
7	Continuous backend performance optimization	7.3	Recurring value, but observability vendors already own distribution
8	Logistics routing optimization	7.1	Clear evaluator and ROI; harder integration and vertical sales
9	Warehouse/inventory/labor optimization	6.9	High value but enterprise implementation burden
10	Building energy/HVAC optimization	6.6	Large value pool, but controls, data, trust, and sales complexity

4. Top 3 Amaura deep dives — interim

4.1 Production agent-evaluation and workflow optimization

Customer: VP Applied AI, Head of AI Platform, or CTO at an AI product company with production agents and meaningful failure, latency, or model-cost exposure.

Problem: Standard answer-level evaluation misses tool-call mistakes, loops, incorrect intermediate actions, cost blowouts, latency regressions, and failures that appear only in

multi-turn or production workflows. Langfuse's own guidance emphasizes trajectory, tool use, task completion, multi-turn behavior, offline datasets, online traffic, and human calibration. Source: [3]

Product: A system that ingests production traces, generates candidate workflow/prompt/tool-routing configurations, executes them against replayable tasks, evaluates outcomes and intermediate steps, and returns the best verified configuration with a regression report.

Pricing hypothesis: $500–$2,000 per month for a small team; $5,000–$20,000 per month for an enterprise deployment with private data, replay infrastructure, and custom evaluators. These are estimates, not observed market averages.

Competition: LangSmith, Braintrust, Langfuse, Maxim, Galileo, Arize, and cloud-provider evaluation platforms. These competitors validate demand but reduce differentiation.

Why Amaura matters: Amaura's search-and-selection loop can move from passive evaluation to **active optimization**. The product should not claim universal agent improvement; it should show improvement on a customer-owned evaluator and held-out set.

MVP: GitHub/SDK integration; trace ingestion; a customer-defined task set; three candidate workflow variants; sandboxed replay; deterministic and model-based evaluators; held-out validation; before/after cost, latency, success, and safety report.

GTM: Founder-led outbound to AI startups with public agent products, job postings for evaluation/platform engineers, or visible reliability issues. Offer a fixed-price evaluation audit and convert a successful audit into a monthly optimization subscription.

Main risk: Evaluators can be gamed or may not reflect production value. The product must include human calibration, unseen cases, and explicit uncertainty.

12-month path: Start with one framework and one workflow class; collect failure traces; add reusable evaluators; productize replay and comparison; then expand into automatic configuration search.

4.2 Coding-agent benchmark and regression infrastructure

Customer: VP Engineering, developer-platform leader, or AI coding-tool company that needs to compare models, agents, prompts, tools, or releases.

Problem: SWE-bench Verified is increasingly questioned as a frontier coding benchmark. OpenAI reported in February 2026 that an audit found many tasks had flawed tests or descriptions and recommended newer benchmarks. SWE-bench Live and SWE-rebench respond with fresher and more continuously generated tasks. Sources: [24] [25] [26]

Product: Continuous private benchmark generation from a customer’ s own repository and issue history, with containerized environments, regression detection, cost tracking, and reproducible agent comparisons.

Pricing hypothesis: $1,000–$5,000 per month for a small engineering organization; $10,000–$50,000 per month for AI-tool vendors or enterprise private deployments. Estimates only.

Competition: OpenAI Evals, SWE-bench variants, Braintrust, LangSmith, E2B, Modal, internal platform teams, and cloud agent platforms.

Why Amaura matters: Candidate agent configurations can be generated and evaluated against fresh, private tasks. The strongest value is not a public leaderboard; it is a decision system that prevents a customer from shipping a worse agent or model.

MVP: One language, one repository family, ephemeral execution through E2B/Modal, issue-to-test conversion, baseline agent, candidate comparison, and a CI-compatible regression report.

Main risk: Execution costs and benchmark quality can overwhelm subscription revenue. The system must cache results, allocate evaluation budgets intelligently, and charge for high-value private evaluation rather than unlimited runs.

4.3 AI-generated-code verification with execution-backed evidence

Customer: CTO or security-conscious engineering leader whose team uses coding agents in production or regulated environments.

Problem: AI code can contain security and quality problems. GitHub itself warns that AI coding output can be insecure or incorrect, while Stack Overflow’ s 2025 survey reported that more respondents distrusted AI-tool accuracy than trusted it. Sources: 4 27

Product: A pre-merge gate that combines deterministic tests, security scans, repository-specific invariants, scenario execution, and an auditable evidence bundle. Amaura can search for test plans, validation configurations, or repair candidates, but the product must never replace deterministic controls with an LLM opinion.

Competition: GitHub Advanced Security, CodeRabbit, Qodo, Greptile, Sonar/Gitar, Aviator Verify, and existing CI/security vendors. Public prices include GitHub Advanced Security at $19 per active committer for Secret Protection and $30 for Code Security; CodeRabbit lists plans from $24 per developer per month annually; Sonar/Gitar lists Core at $20 and Pro at $40 per user per month. Sources: 28 29 30

MVP: GitHub App; required checks; repository-specific invariant templates; sandboxed test execution; risk classification; signed report; human approval; no autonomous production deployment.

Main risk: False positives destroy trust, while false negatives create liability. The product must begin as an evidence and workflow layer, not a guarantee of correctness.

Part II — Cash-Cow Opportunities

1. Market map from preserved research

The preserved research shows five promising cash-cow patterns:

1. **Productized B2B operations services** where documents, reminders, checks, and reporting can be automated.
2. **Specialized research and lead intelligence** where generic data is commoditized but hard-to-find, fresh, verified segments retain value.
3. **Technical production services** such as construction takeoffs, documentation, and proposal work, where human QA remains necessary.
4. **Workflow implementation and automation** for narrow verticals already using email, spreadsheets, and legacy systems.
5. **Managed infrastructure services** such as cloud-cost audits, data monitoring, and developer documentation.

2. Preserved cash-cow opportunities

2.1 Vendor onboarding and procurement operations service

Offer: Fixed-scope supplier intake, document chasing, sanctions/identity and duplicate checks through approved tools, master-data normalization, approval routing, ERP/accounting updates, PO/RFQ follow-up, invoice-exception routing, and weekly KPI reporting.

Buyer: COO, Controller/CFO, Head of Procurement, or AP leader at a 50–500 employee company with 20–200 active suppliers and a lean procurement team.

Evidence: Amazon Business reported that 21% of procurement decision-makers lack systems to monitor/manage supply-chain risk and that 72% outsource procurement to some degree. Apex Analytix described a customer reducing onboarding time from 50 days to 8, but this is a single vendor case study. Sources: 31 32

Alternatives: Gatekeeper, Zip, Procurify, ProcurementExpress, GEP, Genpact, WNS, Vserve, Outsource2india, internal staff, spreadsheets, and ERP modules.

Pricing: Test a $750–$2,000 audit/pilot, then $750–$3,000 per month for a defined supplier-volume/SLA bundle. These are hypotheses. Software alternatives range from $415 to $2,550 per month on ProcurementExpress; offshore services advertise roughly $6–$8 per hour. Sources: 33 34

Margin: Early gross margin likely 40–65%; 50%+ requires automation, narrow scope, templates, and strict exception boundaries.

Amaura adjacency: High evaluator quality because cycle time, completeness, exception aging, duplicate rate, and SLA attainment can be measured. The service can later generate workflow datasets and customer distribution for optimization products.

Main risk: Commodity labor and procurement software can undercut the offer. Sell accountability and exception handling, not generic data entry.

2.2 Specialized lead research and outbound intelligence

Generic list building is commoditized by Clay, Apollo, UpLead, ZoomInfo, Cognism, and agencies. SalesRoads lists an anchor price of $11,950 per four-week SDR program, while Clay lists Launch from $167 per month and Growth from $446 per month. Sources: 35 36

The viable niche is **fresh, evidence-backed research for difficult segments and buying committees**, with explicit validation, source links, trigger signals, and recurring monitoring. A plausible test price is $500–$1,500 for a paid pilot and $1,500–$4,000 per month for recurring refreshes. These are hypotheses, not observed averages.

Main risks are deliverability, compliance, data freshness, and price pressure. Google requires high-volume senders to authenticate, avoid unsolicited email, and enable easy unsubscribe; CAN-SPAM applies to B2B commercial email. Sources: 37 38

2.3 Construction takeoff and estimating overflow service

Construction estimators are difficult to hire: AGC’ s 2025 survey reported that 77% of firms found estimating personnel hard to fill. STACK and Togal.AI both list plans around $299 per user per month, while services advertise prices from roughly $150 per takeoff and $12 per hour. Sources: [39] [40] [41]

The viable model is not raw AI takeoff software. It is a narrow, human-in-the-loop service for one trade and geography, with traceable quantities, addenda monitoring, QA, and an SLA. Major risks are underbidding liability, document ambiguity, seasonality, and low-price competition.

2.4 Freight brokerage back-office automation service

Broker operations involve invoices, bills of lading, proof of delivery, carrier onboarding, exception management, and follow-up. Truckstop describes delays in these workflows as a

cause of slower invoicing and lost business. Transflo claims 75–80% automation and 95–98% accuracy, but these are vendor claims. Sources: [42] [43]

This can work as a narrow managed service for small brokers, but freight-tech competition is intense. Public alternatives include BrokerPro at $950 per month, Rose Rocket from $2,080 per month, AscendTMS from $69 per user per month, and Truckstop RMIS from $340 per month. Sources: [44] [45] [46]

2.5 Compliance evidence collection and reporting service

SOC 2 automation platforms such as Vanta, Drata, Sprinto, and Secureframe address evidence collection, controls, integrations, and auditor workflows. Drata's published cost guide places small/midsize Type I audits around $7,500–$15,000 and Type II around $12,000–$20,000, with total first-year cost potentially much higher. Source: [47]

A small founder should not compete as another compliance platform. A better service wedge is evidence readiness for a narrow stack, with human validation, auditor coordination, and exception resolution. Risks include security liability, changing controls, and trust concerns around automated or templated evidence.

3. Provisional cash-cow ranking

Rank	Opportunity	Speed	Capital efficiency	Recurrence	India/global advantage	Interim verdict
1	Vendor onboarding/ procurement operations	8	8	8	8	Best preser adjace cash c
2	Specialized lead intelligence and monitoring	9	9	7	9	Fastest test; ge versior bad
3	Construction takeoff/estimating overflow	8	8	6	8	Viable with tr specia n and
4	Freight brokerage back-office automation	7	7	8	8	Real pa difficul compe market

5	Compliance evidence readiness service	6	7	8	8	Attract budget trust a liability matter

4. Cash-cow financial scenarios — illustrative, not forecasts

Vendor onboarding/procurement operations

Assumptions: paid pilot of $1,000, then recurring accounts at $1,250–$2,000 per month; founder delivers initially and automates document handling, reminders, normalization, and reporting.

Month	Revenue	Direct costs	Operating profit before founder salary	Reinvestment into Amaura
1	$1,000–$2,000	$300–$800	$200–$1,200	$0–$500
3	$3,000–$5,000	$1,000–$2,000	$1,000–$3,000	$500–$1,500
6	$6,000–$10,000	$2,500–$4,500	$2,000–$6,000	$1,000–$3,000
12	$10,000–$18,000	$4,000–$8,000	$3,000–$10,000	$2,000–$5,000

These ranges assume successful outbound and standardized delivery. They are **speculation**, not market evidence.

Specialized lead intelligence

Month	Revenue	Direct costs	Operating profit before founder salary	Reinvestment into Amaura
1	$500–$2,000	$200–$800	$0–$1,200	$0–$500
3	$3,000–$6,000	$1,000–$2,500	$1,000–$4,000	$500–$2,000
6	$6,000–$12,000	$2,000–$5,000	$2,000–$8,000	$1,000–$4,000

12	$12,000–$25,000	$4,000–$10,000	$4,000–$15,000	$2,000–$7,500

This model has faster testing but more commoditization and deliverability risk.

5. Unit economics — preserved opportunities

Opportunity	CAC hypothesis	ACV / monthly value	Gross margin	Churn assumption	Payback
Agent evaluation optimization	$1k–$10k founder-led	$6k–$60k ARR	65–85% after productization	2–5% monthly	3–12 month
Code verification gate	$1k–$15k	$3k–$50k ARR	60–85%	2–5% monthly	4–15 month
Inference optimization	$5k–$30k	$12k–$150k ARR or savings share	50–80%	Project/annual renewal	3–12 month
Vendor onboarding service	$200–$1,500	$9k–$36k ARR	40–65% early	3–8% monthly	1–4 months
Lead intelligence service	$100–$1,000	$6k–$48k ARR	45–75%	4–10% monthly	1–4 months
Construction takeoff service	$100–$1,000	$150–$2,500 per job or retainer	35–65%	Project/seasonal	1–3 months
Freight back-office service	$500–$3,000	$6k–$30k ARR	35–65%	3–8% monthly	2–6 months
Compliance readiness service	$500–$5,000	$5k–$30k per project/year	40–70%	Annual/project	2–8 months

All figures in this table are rough planning ranges, not verified market averages.

Part III — Hybrid Strategies

1. Amaura first

Upside: maximum technical focus and potential venture scale.
Weakness: no validated customer, evaluator, distribution, or cash flow.
Verdict: only rational if the founder already has a committed design partner and a tightly defined evaluator-rich problem.

2. Cash cow first

Upside: fastest route to revenue and learning about sales.
Weakness: unrelated work can consume the founder and delay Amaura.
Verdict: better than pure Amaura if the cash cow is operationally bounded and has a deadline for productization.

3. Adjacent cash cow

Upside: revenue, customer relationships, workflow data, evaluators, and domain expertise accumulate together.
Weakness: the service may remain a low-margin BPO unless the automation wedge is deliberate.
Verdict: best current strategy.

4. Service → software → Amaura

A procurement or compliance operations service can begin with document extraction, reminders, routing, normalization, and reporting. Once workflow data and measurable outcomes exist, Amaura-like search can optimize policies, exception routing, or staffing decisions. This is more credible than starting with a general optimization platform because the service supplies the evaluator and distribution.

5. Recommended hybrid

Start with **vendor onboarding/procurement operations for a narrow customer segment**, while building an internal evaluator for cycle time, document completeness, exception aging, duplicate detection, and SLA attainment. In parallel, run one paid or tightly scoped pilot for agent evaluation or code-verification infrastructure.

If the operational service reaches repeatable $5k–$10k monthly revenue, reinvest a controlled portion into Amaura. If the technology pilot produces a verified customer-valued improvement, convert it into a separate product. If not, continue improving the service rather than rationalizing the technology.

Part IV — Interim Final Decision

One strongest Amaura business

Production agent-evaluation and workflow optimization.

Why: it fits the generate → execute → evaluate → select → verify loop most naturally; it is recurring; the evaluator can combine deterministic checks with human-calibrated model judges; and customers have a reason to optimize repeatedly as agents, models, tools, and prompts change.

One strongest cash-cow business

Vendor onboarding and procurement operations as a narrow productized service.

Why: it has clear operational pain, recurring volume, measurable outcomes, global delivery potential from India, and a credible service-to-software path. It is not glamorous and is not automatically defensible, which is precisely why it should be sold as a focused outcome rather than built as a broad platform.

One strongest hybrid strategy

Sell vendor-onboarding operations first, automate the repeated workflow, and use the resulting data and evaluators to build optimization products; simultaneously validate agent evaluation with one design partner.

This strategy gives Amaura a chance to earn distribution rather than assuming technology will create it.

Subjective probability estimates

These are **subjective estimates**, not facts, and reflect an India-based founder with limited capital, no large sales team, and no proprietary frontier model.

Path	First $1k revenue	$10k MRR	$1M ARR	Venture-scale

Agent-evaluation optimization	35%	18%	8%	5%
Code-verification infrastructure	30%	15%	7%	5%
Vendor-onboarding cash cow	65%	35%	10%	3%
Specialized lead intelligence	70%	40%	8%	2%
Recommended hybrid	60%	40%	15%	8%

The hybrid has a higher chance of producing useful cash and a credible technology wedge, but it has a meaningful execution risk: the founder may become trapped in service delivery.

What to build in the next 30 days

Week 1

- Pick one vendor-onboarding segment, such as US/UK/AU SaaS, agencies, or multi-entity services firms.
- Define a fixed pilot: 10–25 suppliers, two-week turnaround, clear deliverables, client-owned systems, and no autonomous approval of high-risk vendors.
- Build a one-page offer around cycle time, completeness, exception aging, and auditability.
- Create a list of 100 target companies using supplier growth, procurement hiring, ERP migration, audit, or M&A signals.

Week 2

- Contact 20–30 qualified prospects per day through personalized email and LinkedIn.
- Contact fractional CFOs, ERP implementers, procurement consultants, and compliance firms for referrals.
- Offer a paid pilot or a tightly scoped diagnostic, not free open-ended consulting.
- Interview at least 10 AI-platform leaders about agent-evaluation failures and current tooling.

Week 3

- Deliver the first pilot manually but record every document type, exception, decision, and time measurement.
- Automate extraction, reminders, deduplication, and weekly reporting.
- Define a held-out evaluator for the operations workflow.
- Build a small agent-evaluation prototype using one customer-owned task set.

Week 4

- Convert the pilot into a monthly SLA retainer if the outcome is measurable.
- Decide whether the first internal automation saves enough time to justify productization.
- Secure one agent-evaluation design partner or stop active Amaura product development until a partner is found.
- Set a hard weekly time budget for service delivery and protect the remainder for product work.

90-day plan

By day 90, the target should be:

- 2–5 paying operations customers;
- at least $3k–$10k monthly revenue, if outbound works;
- documented delivery costs and gross margin;
- one repeatable workflow with 50%+ of routine steps automated;
- one agent-evaluation or code-verification pilot with a real user;
- a held-out benchmark showing whether Amaura improves a customer metric;
- a decision on whether to continue, narrow, or kill the product wedge.

Kill criteria

- **If 100 well-targeted prospects produce no paid pilot or serious procurement conversation, stop or change the niche.**
- **If a pilot cannot show a measurable before/after improvement within two weeks, stop selling that offer.**

- **If delivery requires more than 50% manual labor after three customers, narrow the scope or stop productization.**
- **If the Amaura pilot cannot beat a simple baseline on a held-out evaluator after three serious iterations, stop calling it a product advantage.**
- **If customers only want labor at commodity rates, stop and choose a higher-value niche.**

Bottom line

The preserved evidence does **not** justify claiming that Amaura has already found a venture-scale business. It does justify a focused commercial experiment around evaluation-rich optimization infrastructure.

The strongest near-term plan is not "build an AI that discovers algorithms." It is:

> **Sell a narrow operational outcome, create a reliable evaluator, automate the repeated work, and use that distribution and evidence to test whether Amaura can improve a valuable customer process.**

That is a credible business-building path. A broad platform-first approach would currently be rationalization of an interesting technical project rather than a validated company thesis.
